

# Online Appendix

## Parental Leave, (In)formal Childcare and Long-term Child Outcomes

This Online Appendix provides additional material discussed in the paper ‘Parental Leave, (In)formal Childcare and Long-term Child Outcomes’ by Natalia Danzer, Martin Halla, Nicole Schneeweis, and Martina Zweimüller, published in the *Journal of Human Resources*. This document comprises two sections. The first section (A.1) discusses the effects of the PL reform on educational performance. The second section (A.2) contains additional estimation results.

### A.1 Effects of the PL reform on educational performance

#### A.1.1 Data

To assess the effect of the Austrian PL reform from 1990 on educational outcomes, we use PISA data from 2003 and 2006 and data from the *Educational Register* of the city of Linz (EducReg).<sup>1</sup> These data sets have several drawbacks compared with the register data that we use in our main analysis. First, these data do not cover the universe of births. PISA includes a representative sample of about 5,000 children aged 15/16 years at the time of testing. Thus, in PISA 2006 the 1990 birth cohort was sampled and in PISA 2003 we observe the 1987 birth cohort. The EducReg includes all children residing in Linz. Second, since these data do not include information on the mother’s eligibility or actual PL takeup, we can only estimate ITTs. Third, we cannot impose the same sample restrictions, because these data sets lack information on birth order, multiple births, and the exact birth date (only the month of birth is available). Since the EducReg provides no information on the child’s country of birth, we exclude all students with foreign language or citizenship.<sup>2</sup> Fourth, we adapt our econometric model, since we can not include trends in the running variable (birthdate). Fifth, the set of covariates is

---

<sup>1</sup>Linz is the third-largest city of Austria and the capital of the state of Upper Austria. Upper Austria is one of nine federal states in Austria. It comprises about one sixth of the Austrian population and workforce.

<sup>2</sup>This sample restrictions aims to exclude children, who were potentially not exposed to the Austrian PL system. Austria witnessed a large influx of migrants post 1993.

smaller. Sixth, the PISA and EducReg lack information on community of birth. Instead, our analysis of the EducReg is based on all children residing in Linz (at the time when we measure educational outcomes). While we know that nurseries were available in Linz in 1990, we do not know whether each of these children was actually born in a community with a nursery. In our analysis of the PISA data we observe the size of the community (in bands) in which the school is located and use a cutoff of 100,000 inhabitants to stratify the sample (since neither the community of birth nor the community of residence is observed). We know that communities with more than 100,000 inhabitants had a nursery in 1990, whereas almost all communities with fewer than 100,000 did not. Given these data restrictions, the results with respect to treatment effect heterogeneity have to be interpreted with caution.

### **A.1.2 Children’s educational outcomes**

We analyze PISA test scores in the fields of mathematics, science, and reading achieved at age 15/16. Further, we check which school track the child attended in grades 8 and 9. This information is contained in the EducReg sample (Linz) (grade 8) and the PISA data (grade 9), respectively. Table A.1 provides a description of the outcome variables.

Note that Austria has a system of early tracking. After primary school, students are allocated to two educational tracks. Higher secondary schools (the *high track*) comprise grades 5 to 12/13, provide advanced education, and conclude with a university entrance exam. Lower secondary schools (the *low track*) comprise grades 5 to 8, provide basic general education, and prepare students for vocational education either within an intermediate vocational school or within the dual education system. The dual education system combines an apprenticeship in a firm and (vocational) education at a vocational school. In the EducReg sample (Linz), we observe school tracks in grade 8. About 39 percent are in the high track, respectively. This share is above the national average (30 percent).<sup>3</sup> In the PISA sample, which covers students in grade 9 and is representative of Austria, about 63 percent of students are in the high track.<sup>4</sup>

---

<sup>3</sup>Data for the school year 2005/06 show that around 30 percent of all Austrian children attended the high track in grade 8. This share was higher in urban areas, 37 percent in Linz and 46 percent in Vienna (Schneeweis and Zweimüller, 2012).

<sup>4</sup>Data for the school year 2006/07 show that after grade 8 about a third of graduates from the low track transfer to the high track (Schneeweis and Zweimüller, 2012).

**Table A.1: Description of children’s educational outcome variables**

Outcome	Variable description	Data source <sup>a</sup>	N	All Mean	Communities	
					with nurseries Mean	w/o nurseries Mean
Test score math	This variable captures the tests core in mathematics (age 15/16).	PISA	1,405	522	526	520
Test score science	This variable captures the tests core in science (age 15/16).	PISA	1,405	519	520	517
Test score reading	This variable captures the tests core in reading (age 15/16).	PISA	1,405	506	510	503
High track grade 8	Binary indicator equal to one if child is in the high track in grade 8 (age 13/14).	EducReg	456	-	0.386	-
High track grade 9	Binary indicator equal to one if child is in the high track in grade 9 (age 14/15).	PISA	1,386	0.560	0.630	0.526

Notes: <sup>a</sup>PISA = Programme for International Student Assessment, EducReg = *Educational Register* of the city of Linz

### A.1.3 Empirical strategy

Since the data do not contain information on actual maternal PL duration, we estimate the following intention-to-treat effects:

$$O_i = \gamma_0 + \gamma_1 T_i + \gamma_2 A_i + \mathbf{x}_i \phi' + \tau_c + \omega_i \quad (3)$$

### A.1.4 Educational outcomes: Average effects

Our complementary analysis on educational outcomes does not reveal any significant effects of the PL in the full sample (see Table A.2). The ITT estimates suggest that, on average, the PL extension did neither significantly affect PISA test scores nor the likelihood of high track attendance in secondary school. These results are robust to the exclusion (column 2) or addition of a rich set of covariates (column 3) and to the exclusion of children with foreign-born mothers from the sample (column 4). However, it is important to keep in mind that these estimations are based on much smaller samples and include children whose mothers were not eligible to PL. All coefficients on the PISA test scores have a positive sign and correspond in size to about

8 to 10 percent of a standard deviation, but are too imprecisely estimated to be statistically significantly different from zero.

**Table A.2: Average child educational outcomes**

	(1)	(2)	(3)	(4)
	Baseline	No covariates	More covariates	Exclude migrants
Test score math (age 15/16)	13.168 (10.880)	8.646 (11.438)	10.398 (12.206)	8.422 (11.546)
Test score science (age 15/16)	11.487 (11.274)	8.540 (11.865)	7.361 (12.829)	7.221 (11.767)
Test score reading (age 15/16)	9.806 (11.159)	8.180 (12.012)	8.036 (12.587)	6.298 (11.796)
High track grade 9 (age 14/15)	0.022 (0.048)	0.019 (0.051)	-0.019 (0.054)	0.006 (0.050)

Each coefficient represents a separate regression based on survey data from *PISA*. Coefficients represent reduced form estimates. We use a sample of children born in Austria in June/July 1987/1990. In the baseline specification, presented in column (1), we control for the child's sex, low maternal SES (based on education), whether the mother was born abroad and birth-year and birth-month fixed-effects. Column (2) includes only controls for birth-year and birth-month. Column (3) includes additional indicators for maternal occupation and skills (4 groups) and the maternal socioeconomic index of occupational status (ISEI). Column (4) drops all foreign-born mothers from the sample. Robust standard errors are shown in parentheses. Estimations control for the survey design (school clusters, student weights). \*, \*\* and \*\*\* indicate statistical significance at the 10-percent, 5-percent and 1-percent level.

### A.1.5 Educational outcomes: Heterogeneity analysis

The heterogeneity analysis by availability of nursery at the time of birth yields similarly striking differences (despite the inferior data quality). As the results in Table A.3 suggest, the PL reform significantly improved the educational outcomes in communities without nurseries, but had zero to negative effects on educational performance in communities with nurseries.

As regards the PISA test scores, the estimated effects on the test scores in science and reading differ significantly between communities. In communities with childcare facilities, the coefficients are negative for all three subjects, although statistically significant only in reading. By contrast, we obtain positive and statistically significant effects in communities where childcare is unavailable. The positive coefficients on the test scores amount to about one quarter of the standard deviations in these variables. In addition to the test scores, we investigate high track attendance in different grades; however, we do not find any significant effects in grade 9. By contrast, significant negative effects are obtained for high track attendance in grade 8

in Linz (a community with a nursery). These results are robust to adjustments in the set of covariates and in the sample specification (see Table A.4).

**Table A.3: Children’s educational outcomes by availability of nursery (proxy)**

	Communities with nursery <sup>a</sup>	Communities w/o nursery <sup>b</sup>	P-value $\Delta^c$
Test score math (age 15/16)	-11.833 (21.431)	21.712* (12.527)	0.179
Test score science (age 15/16)	-27.516 (20.216)	23.435* (12.811)	0.032
Test score reading (age 15/16)	-39.839** (20.274)	27.161** (12.627)	0.005
High track grade 9 (age 14/15)	0.027 (0.094)	0.012 (0.056)	0.891
High track grade 8 (age 13/14)	-0.213** (0.091)		

Notes: Each row represents a separate regression based on survey data from *PISA* and register data from *EducReg Linz*. Estimation results are based on fully interacted models. Coefficients represent reduced form estimates. We use a sample of children born in Austria in June/July 1987/1990 in *PISA* (1989/1990 in *EducReg*). Each specification controls for the child’s sex, low maternal SES, whether the mother was born abroad (only *PISA* sample) and birth-year and birth-month fixed-effects. Robust standard errors are shown in parentheses. Estimations for *PISA* education outcomes control for the survey design (school clusters, student weights). \*, \*\* and \*\*\* indicate statistical significance at the 10-percent, 5-percent and 1-percent level. <sup>a</sup>The child attends a school in a community with  $\geq 100,000$  inhabitants. <sup>b</sup>The child attends a school in a community with  $< 100,000$  inhabitants. <sup>c</sup> $\text{Prob} > F(\text{chi}^2)$  of diff. in coefficients between communities with and w/o nursery.

**Table A.4: Sensitivity: Children’s educational outcomes by availability of nursery (proxy)**

	Communities <b>with</b> nursery <sup>a</sup>				Communities <b>w/o</b> nursery <sup>b</sup>			
	(1) Baseline	(2) No covariates	(3) More covariates	(4) Exclude migrants	(1) Baseline	(2) No covariates	(3) More covariates	(4) Exclude migrants
Test score math (age 15/16)	-11.833 (21.499)	-25.090 (23.219)	-26.898 (21.129)	-27.656 (24.018)	21.712* (12.536)	19.500 (13.228)	19.157 (14.245)	19.914 (13.015)

**Table A.5: Overview: PL reforms and child outcomes**

Study	Country and year of reform	Content of reform	Assessed child outcomes & data	Results	Mode of non-parental childcare
Baker and Milligan (2010)	Canada 31 December 2000	Extension of maternity leave benefits from 25 to 50 weeks. Extension of j.p. PL from 18-70 to at least 52 weeks in all regions.	Parent-reported measures (temperament, motor and social development) at age: 7 and 24 months. <i>Data:</i> survey data (NLSCY)	Small and mostly insignificant results. <i>Heterogeneity:</i> Not tested.	Mainly informal care (40% for under-2-year-olds). Formal care rare (4/6% of children younger than 1/2 year/s).
Baker and Milligan (2015)	Canada 31 December 2000	see Baker and Milligan (2010)	Cognitive development (vocabulary, numbers), parent-reported measures (eg hyperactivity) at age: 4/5 years. <i>Data:</i> survey data (NLSCY)	No significant positive effects. Small negative effects on vocabulary scores. <i>Heterogeneity:</i> Same across subgroups (gender, parental education).	see Baker and Milligan (2010)
Carneiro, Løcken and Salvanes (2015)	Norway 1 July 1977	Introduction of paid PL for 18 weeks (100% income replacement) Extension of unpaid j.p. PL from 12 weeks to 12 months	High school dropout, college attendance, earnings at age 30, years of schooling, IQ (males age 18-19), teenage pregnancy <i>Data:</i> Administrative data	Significant positive effects: Reduced drop-out rates and increased earnings, college attendance, completed years of schooling and IQ (males) <i>Heterogeneity:</i> Differential effects by maternal education, gender, birth order, rural/urban location and distance to grandparents.	Mainly informal care. Formal childcare rare (1-2% for under-2-year-olds).
Dahl, Løcken, Mogstad and Salvanes (2016)	Norway Six PL reforms: 1 May 1987 – 1 April 1992.	6 extensions of paid PL by 2 to 4 weeks each during the first year of life (at 100% income replacement).	Compulsory exam at end of junior high school, high school dropout <i>Data:</i> Administrative data	No significant effects. <i>Heterogeneity:</i> Not tested.	Mainly informal care. (see Carneiro et al. 2015)
Danzer and Lavy (2018)	Austria 1 July 1990	Extension of paid+j.p. PL from child's 1st to 2nd birthday.	Test scores in reading, math and science at age 15/16. <i>Data:</i> PISA	No significant average effects. <i>Heterogeneity:</i> Significantly positive effects for sons of highly educated mothers.	Mainly informal care. Formal childcare for under-3-year-olds rare (<3%).
Dustmann and Schönberg (2012)	Germany Three PL reforms: 1 May 1979 1 January 1986 1 January 1992	Extension of paid+j.p. PL from 2 to 6 months (flat rate; 1979), from 6 to 10 months (means-tested; 1986) Extension of unpaid j.p. PL from 18 to 36 months (1992).	Wages, educational attainment (age 28/29; 1979 reform), graduation from academic track (1986 reform), school track (age 14; 1992 reform) <i>Data:</i> Administrative data	No or extremely small effects. Expansion from 18 to 36 months slightly negative effects. <i>Heterogeneity:</i> Not tested.	Mainly informal care. Enrolment in formal care low (5% for under 18-months-olds).
Liu and Nordstrom Skans (2010)	Sweden 1 August 1988 – 1 October 1988	Gradual extension of paid PL from 12 to 15 months (by 30 days in each of 3 consecutive months 08/09/10 1988).	Test scores during last compulsory school year, compulsory school grades at age 16 <i>Data:</i> Administrative data	No significant effects. <i>Heterogeneity:</i> Positive effect for children from mothers with higher education.	Mainly formal care (40-50% of children aged 1-2). Few children in informal care.
Rasmussen (2010)	Denmark 26 March 1984	Extension of paid PL from 14 to 20 weeks	High school enrolment, GPA, reading scores at age 15/16 <i>Data:</i> Administrative data, PISA	No significant effects <i>Heterogeneity:</i> Same across subgroups (gender, parental education).	Mainly formal day care even for very young children.

*Abbreviations:* j.p. - job-protected; NLSCY - National Longitudinal Study of Children and Youth; PL - PL; PISA - Programme for International Student Assessment.

Fit for military (boys)	0.111 (0.083)	-0.034 (0.087)	0.130	0.082 (0.059)	0.158*** (0.052)	0.326

*Notes:* Estimation results are based on fully interacted models, estimated separately for mothers living in communities with and without nursery. Coefficients are based on 2SLS estimations, with years on PL instrumented by the assignment to the reform (both interacted with indicators for mothers with low and high SES). We use local linear regressions including triangular weights and separate linear trends on each side of the discontinuity. We use a bandwidth of 30 days, exclude children born  $\pm 5$  days around the cutoff date, and control for the child's sex, low maternal SES, maternal age groups, whether the mother was born abroad, and whether the child was a pre-term birth. Standard errors (shown in parentheses) are clustered at the community level. \*, \*\* and \*\*\* indicate statistical significance at the 10-percent, 5-percent and 1-percent level. <sup>a</sup>Maternal socioeconomic status is based on maternal education and pre-birth earnings (low: compulsory, apprenticeship training or intermediate vocational school plus below median pre-birth earnings, missing education; high: apprenticeship training or intermediate vocational school plus above median pre-birth earnings and at least higher secondary education). <sup>b</sup>Prob>F(chi2) of difference in coefficients between mothers with high and low SES.

Notes: Estimation results are based on fully interacted models, estimated separately for mothers with low and high work propensity. Coefficients are based on 2SLS estimations, with years on parental leave instrumented by the assignment to the reform (both interacted with indicators for communities with and without nursery). We use local linear regressions including triangular weights, a bandwidth of 30 days (excluding children born  $\pm 5$  days around the cutoff date) and separate trends on each side of the discontinuity. Unless otherwise indicated, we control for a vector of pre-determined variables  $\mathbf{x}$  (child's sex, low maternal SES, maternal age groups, whether the mother was born abroad, and whether the child was a pre-term birth). Standard errors (shown in parentheses) are clustered at the community-level. \*, \*\* and \*\*\* indicate statistical significance at the 10-percent, 5-percent and 1-percent level. <sup>a</sup>Maternal characteristics indicate a low/high propensity of being employed  $> 0$  days in the second year after childbirth, low/high according to median prediction (0.51). <sup>b</sup>Prob $>F(\chi^2)$  of difference in coefficients between mothers living in communities with and without nursery based on fully interacted regressions. <sup>c</sup>Excludes vector of predetermined covariates  $\mathbf{x}$ . <sup>d</sup>Additional covariates: maternal daily real wage (mean over last 2 years before child birth), maternal occupation (white-collar/civil servant, blue-collar, self-employed/farmer), whether the mother was married, maternal education (6 indicators), maternal religious denomination (5 indicators), province (8 indicators), and whether the child had low birth weight. <sup>e</sup>Additional community-level covariates: population size, population density, share of catholics, share of votes for conservative parties, share of married, share of pop. betw. 0 and 5 years, share of pop. betw. 0 and 15 years, female employment rate, female fulltime employment rate, availability of a higher secondary school and number of classes in higher secondary school. <sup>f</sup>Quadratic trends in the running variable. <sup>g</sup>Excludes foreign-born mothers from the sample. <sup>h</sup>Bandwidth of 61 days on each side of the discontinuity (excluding children born  $\pm 5$  days around the cutoff date) <sup>i</sup>Maternal characteristics indicate a low/high propensity of being employed  $\geq 180$  days in the second year after childbirth, low/high according to median prediction (0.34).

We use local linear regressions including triangular weights and separate linear trends on each side of the discontinuity. We use a bandwidth of 30 days, exclude children born  $\pm 5$  days around the cutoff date, and control for the child's sex, low maternal SES, maternal age groups, whether the mother was born abroad, and whether the child was a pre-term birth. Standard errors (shown in parentheses) are clustered at the community level. \*, \*\* and \*\*\* indicate statistical significance at the 10-percent, 5-percent and 1-percent level. <sup>a</sup>Prob>chi2 of difference in coefficients between communities with and w/o nursery. <sup>b</sup>Maternal employment is measured in January following the child's birthday in each year.

*Notes:* Data from the OECD Family Database (PF2 5: Trends in leave entitlements around childbirth, updated November 2019). Note that the expression paid *child-related leave* is an umbrella term for policies granting parents the right to paid child-related leave, which includes maternity leave, parental leave, and other forms of child-related leave, e.g., cash-for-care transfers or home-care subsidies. Information refers to weeks of paid maternity leave and any weeks of paid parental leave and paid home care leave (sometimes under a different name, for example, *childcare leave* or *child raising leave*) that are available to mothers. Data reflect entitlements at the national or federal level only (no regional-specific entitlements). Several countries allow spreading leave benefits over a longer period ('long-option').

**Table A.20: Employment rates of mothers (not absent on leave) of children aged 0 to 2 and formal and informal childcare enrolment of 0-2-year-olds (in 2014)**
